

Web Hosting

Steps to reduce CPU resource Usage

1. Use a Cache Plugin

2. Kill Spam

Use third party comment system

When things are critical or even if your blog has a high traffic, you must adopt a third party comment system such as discuss, livewire or Facebook/G+. When a reader/visiter submits a comment at your blog, the system needs to insert the texts in your MYSQL database and that creates a hell lot of load for CPU & if your DB is large or if it is corrupted or if the system is getting multiple requests simultaneously, things will go worse.

3. Stay Updated:

Never hesitate to update your Wordpress, plugins or themes.

On regular interval the developer find & fix the bug & release the latest version of WordPress & its plugins/theme.

I strongly recommend you to stay updated with all the applications /plugin/themes you are using at your Wordpress blog.

4. Remove unnecessary plugins

5. Reduce load on index.php file

- Reduce the number of posts on homepage

Web Hosting

- Always use excerpts for displaying posts on homepage
- Remove image files from homepage & unnecessary links
- Would be better if you use a CDN service

Unique solution ID: #1075
